Abstract
The objective of project is to use vapour absorption system instead of vapour compression system. In this project is to reduce the fuel consumption by using of exhaust gas waste heat. This work presents an experimental study refrigeration system, using vapour absorption system. This system uses the exhaust waste heat of an internal combustion engine as energy source. The system was found to be applicable and ready to produce the required conditioning effect without any additional load to the engine. The proposed system decreases vehicle operating costs and environmental pollution caused by the heating system as well as causing a lower global warming.

Keywords: Waste heat, Refrigeration, Vapour absorption system and Internal Combustion Engine

INTRODUCTION
The term refrigeration is a broad sense is used for the process of removing heat (i.e. Cooling) from a substance. It is also includes the process of reducing and maintain the temperature of body below the general temperature of its surrounding. This project consists of an Electrolux refrigeration system using heat engine energy as input. The principle behind Electrolux refrigeration is that it uses three gases to accomplish its cooling effect namely ammonia (refrigerant), water (absorbent) and hydrogen. Ammonia is used as refrigerant as it is easily available, environmental friendly and can produce a better cooling effect. The refrigerator is invented in the car. The engine heat is supplied to the refrigerator and input heat is required at the generator where aqua ammonia is heated to get ammonia vapors. In this project, an experimental setup for Electrolux refrigeration is made using waste heat produced from engine.

2. MAIN SECTION

2.1 Refrigeration
Refrigeration is the process of removing heat from a body. The removed heat is moved to a place where it does not affect the working system. The main objective of refrigeration is to reduce heat to a lower temperature and maintaining it at that temperature. The term cooling refers generally to any natural or artificial process by which heat is dissipated.

2.1.1 Coefficient of Performance (COP)
The coefficient of performance, of a refrigeration system is the ratio of the heat removed from the cold reservoir to input work.

\[ \text{COP}_{\text{cooling}} = \frac{|\Delta Q_{\text{cold}}|}{\Delta W} \]

\( \Delta Q_{\text{cold}} \) = the heat moved from the cold reservoir (to the hot reservoir).
\( \Delta W \) = is the work consumed by the heat pump.

2.1.2 Unit of Refrigeration
Refrigerators are rated in kJ/s, or Btu/h of cooling. One ton of refrigeration capacity can freeze one ton of water at 0 °C (32 °F) in 24 hours.

Based on that:

\[ 1 \text{ ton of refrigeration} = 200 \text{ Btu/min} = 3.517 \text{ kJ/s} \]

2.1.3 Methods of Refrigeration
Methods of refrigeration can be classified as
i. Cyclic
ii. Non-Cyclic
iii. Thermoelectric

Cyclic Refrigeration can be classified as:
1. Vapor cycle, and
2. Gas cycle
Vapor cycle Refrigeration can further be classified as:
1. Vapor compression refrigeration
2. Vapor absorption refrigeration

Vapor Absorption Cycle
The working of absorption cycle is, the mixture of refrigerant and absorber i.e. strong solution is pumped to the generator using a small pump. The generator is the main unit of the whole refrigeration system. In generator heat is supplied to the strong solution. By using this heat refrigerant is separated from the mixture of strong solution and it forms vapours. The remaining weak solution flows back into the absorber.

![Vapour Absorption System Diagram](image)

3. COMPONENTS
The refrigeration system comprises of various components. They are as follows,
1. Condenser
2. Evaporator
3. Heat Exchanger
4. Refrigerant
5. Absorbent

3.1 Condenser
The condenser is used in the high pressure side of the system. The heat of refrigerant vapour is transferred to the walls of condenser and then to the cooling medium. In our work we used fin and tube condenser.

3.1.1 Fin and Tube Condenser
The Fin and Tube condenser is one in which the removal of heat is done by air. It consists of steel or copper tubing through which the refrigerant flows. The size of the condenser should be made of aluminium because of its weight. The condensers with the single row of tubing provide the most efficient heat transfer. This is because the air temperature rises as it passes through each row of tubing.

3.2 Evaporator
The evaporator is used in the low pressure side of the refrigeration system. The evaporator absorbs heat from the surroundings which is to be cooled. This heat is transferred to the liquid refrigerant. At this place the liquid refrigerant becomes a vapour. To make the heat absorption from the surrounding easy, the temperature of evaporator is always less than the surrounding.

3.2.1 Shell and Coil Evaporator (Cold Tank)
The shell and coil evaporators are used to chill water. It is also known as dry expansion evaporators. The cooling coil may be spiral or double spiral. The shell sealed or open depends on the need.

3.3 Heat Exchangers
Heat exchangers transfer heat, mainly from one fluid to another fluid. They are also used in cooling applications like air conditioners, refrigerators. In parallel flow heat exchangers both the fluid moves in same direction. In cross flow heat exchanger, the fluids flow perpendicular to one another.

Types of Heat Exchangers
1. Shell and Tube Heat Exchanger
2. Plate Heat Exchanger
3. Regenerative Heat Exchanger
4. Adiabatic Wheel Heat Exchanger

In this project we used shell and tube heat exchanger.

3.3.1 Shell and Tube Heat Exchanger
The liquid flows through multiple tubes of shell and tube heat exchangers. There are two sets of tubes. One contains the liquid to be heated or cooled and the other contains liquid for performing heat exchange. The wall thickness and diameter should be made correct to make effective heat exchange.

3.3.2 Heat Transfer Considerations
The heat is transferred by convection in inner and outer side of inner tube. Heat transferred through conduction across the tube. The hot stream is in bigger diameter tube and energy flows between cold and hot streams.
3.4 Refrigerants

A refrigerant is a substance that absorbs heat from required body or substance. Example: water, ice, air. Etc.

3.4.1 Selection of Refrigerant

The thermodynamic, physical as well as safe working properties should be taken in to account before selecting a refrigerant for a particular purpose. There is no single best refrigerant which can be used for all refrigeration purposes.

The following properties must be taken in to account before selecting the refrigerant,
1. Working pressure range and pressure ratio
2. Corrosiveness and flame ability
3. Space limitation
4. Temperature required in the evaporator

The refrigerant used in our work is ‘Ammonia’.

3.4.2 Ammonia

Ammonia is the only refrigerant from inorganic group which was used universally for many applications and still used to great extent at the present time. It possesses many properties required for an ideal refrigerant. It has wide applications because of its low volumetric displacement, low cost, low weight of liquid refrigerant per ton of refrigeration and high efficiency. Presently it is widely used in cold storages, ice manufacturing plants and skating rinks due to its low production and maintenance cost.

Properties of Ammonia

1. Its toxic, flammable, irritating and food destroying
2. Anhydrous ammonia has no effect on lubricating oil but in presents of moisture, ammonia forms an emulsion with oil that causes operating difficulties. The formed emulsion becomes effective when the percentage of water exceeds 0.01%. It is not oil miscible therefore it will not dilute the oil in the crank case of the compressor.
3. It is highly volatile and becomes explosive when mixed with air and compressed therefore air leaks must be avoided in ammonia refrigeration systems.
4. Ammonia attacks on non-ferrous metals in the presents of water therefore copper and brass are never used with ammonia refrigeration system.
5. Ammonia can be used economically for -70°C evaporator temperature and its application for further low temperature becomes highly uneconomical and difficult to maintain low vacuum required in the evaporator.

The following table represents properties of ammonia.

Design Conditions for the Aqua Ammonia Refrigeration System:

The values for the design of the Aqua Ammonia vapour absorption system are:

Specification of system:
Model: RB40
Net volume: 40 liters
Input voltage: 220-240V, 50Hz
Power: 65W
Refrigerant: NH3
Mass of ammonia: 72gm
Temperature of the evaporator, $T_e = 8^\circ C$
Condenser pressure, $P_c = 8$ bar
Evaporator pressure, $P_e = 1$ bar
Temperature of the Condenser, $T_c = 40^\circ C$
Temperature of the Generator, $T_g = 95^\circ C$
Heat obtained from engine waste heat: 165°C

The corresponding pressure required can be noted from the refrigeration table of ammonia (R-717)

In this way, the condenser pressure is fixed at $P_c=8$bar

Evaporator temperature =8 °C required to be maintained in the evaporator chamber and evaporator pressure is kept
equal to the atmospheric pressure (1 bar), to ensure design economy.

\[ h_1 = 1620 \text{ KJ/Kg for } P_c \text{ at 8 bar} \]
\[ h_2 = h_3 = 430 \text{ KJ/Kg for } P_c \text{ at 8 bar} \]
\[ h_4 = 1570 \text{ KJ/Kg for } P_e \text{ at 1 bar} \]

**Cop Of The System (Actual):**

The actual cop of the refrigerating unit can be calculated by using the equation,

\[ \text{Cop} = \frac{(T_e (T_g - T_c))}{(T_g (T_c - T_e))} \]
\[ = \frac{8(95-40)}{95(40-8)} \]
\[ = 0.22 \]

**Ton of Refrigeration:**

For ammonia,

\[ Q_1 = mC_p \Delta T = (0.072 \times 4.7 \times 8) \]
[Since Cp of ammonia is 4.7 KJ/KgK]
\[ = 2.707 \text{ KJ/min} \]

\[ Q_2 = mh_f g = 0.072 \times 1369 \]
[Since Latent heat of vaporization of ammonia is 1369 KJ/Kg]
\[ = 98.568 \text{ KJ/min} \]

\[ \text{TR} = \frac{(Q_1+Q_2)}{210} \]
\[ = 0.48 \text{ ton of refrigeration} \]

**Mass Flow Rate:**

Say the mass flow rate of ammonia in evaporator be Mr

Therefore,

\[ Mr = 0.5 \frac{TR}{(h_4-h_3)} \]
\[ = 0.5 \frac{(210)}{(1570-430)} \]
\[ = 0.092 \text{ KJ/min} \]

**Heat Absorbed From Aqua Ammonia Solution:**

The amount of heat of absorption is a function of the concentration of aqua and it is given by molier equation as

\[ Q_a = 802.5(1-x_w)-928x_w^2 \]
\[ = 802.5(1-0.35)-928(0.35)^2 \]
\[ = 407.945 \text{ KJ/Kg} \]
[Since concentration of water x_w =0.35 from the H-C chart]

**Mass of Water:**

\[ X_w = \frac{\text{mass of NH}_3}{(\text{mass of ammonia +mass of water)}} \]
\[ = 0.35 \]
\[ = 0.072/(0.072+mw) \]
\[ M_w = 0.133 \text{ Kg} \]

the concentration of strong aqua solution becomes

\[ x_s = x_w + mr \]
\[ = 0.35 + 0.092 = 0.442 \]

Using material balance equation,

\[ (mw+mr)x_s = mrx + mwx_w \]
\[ (mw+0.092)(0.442) = (0.09x1) + (mwx0.35) \]

Mass flow rate of water(Mw)=0.56 Kg/s

**Theoretical Cop of the System:**

\[ \text{Cop} = \frac{\text{Refrigerant effect}}{\text{heat input}} \]
\[ = \frac{\text{QE}}{\text{QG}} \]
\[ \text{QG} = mr (h_4-h_3) \]
\[ = 0.092(1570-430) \]
\[ = 102.6 \text{ KJ/min} \]

Now,

\[ \text{Theoretical COP} = \frac{(102.6)}{(257.8)} \]
\[ = 0.399 \]

**RESULTS:**

**i.** Condenser pressure : 8 bar
**ii.** Evaporator pressure : 1 bar
**iii.** Heat input required at generator : 257.8 KJ/min
**iv.** Outlet temperature of exhaust gas : 165°C
**v.** Actual COP of the system : 0.15
**vi.** Theoretical COP of the system : 0.399

4.1 Result and Discussions
Fig. 4 shows the time variation of the evaporator temperature. From the above figure, it is observed that evaporator temperature decreases with time. It is depending on engine valve opening, the refrigeration system reaches the steady state condition and its interior starts cooling down, leading to the reduction of the evaporator average temperature. The temperature dropped faster inside the refrigerator as the throttle valve opening was wider. Attainment of the refrigerator steady state temperature was faster as the engine throttle valve was widened. Overall, the refrigeration average internal temperature took around 3–3.5 h to reach the steady state condition. The wider the valve opening, the lower the steady state average temperature attained inside the refrigerator. This temperature varied between 5°C and 13°C from a dedicated system. The absorption refrigeration system was shut down after approximately 3 h, when the steady state temperature was attained.

Table 3 shows the time variation of the coefficient of performance of the system until system shut down after the steady state condition was attained. The maximum coefficient of performance was 4.9%, for 25% open throttle. For all other valve opening, the peak coefficient of performance attained was even lower, of about 1.2–1.4%.

5. CONCLUSION

The coefficient of performance of the system is low, that means that the system is expected to use a lot of energy with respect to the cooling it offers. But this is not a disadvantage in the case of our air-conditioner. This is because the energy we use is the engine waste heat energy which is available in automobile vehicles. Also, this safeguards the interest of the future generations who would be able to get air conditioning without use of electricity also. This is going to make the operational cost of the air conditioner very low. Moving parts are also not there in the system. Noise and vibrations are decreased to a minimum. Ammonia is a very cheap gas. This reduces the cost of the system. Waste heat is all what is needed for the system to operate. This project hence has a very bright future in the commercial market as well as in the industrial market.

ACKNOWLEDGEMENTS

This work was supported by Department of mechanical Engineering in Knowledge institute of technology. We are extremely grateful to thank our principal Dr.PSS.Srinivasan for providing all facilities to complete this project. The authors appreciate the support of Dr.K.Visagavel, Professor & Head- Department of Mechanical Engineering and Mr.A.Selvakumar, Asst. Professor, Mech.
